

Week1 Memo – Ednah Kimani

Audience: Senior Manager

This week I developed a small operational tracking tool designed to monitor performance across different hospital wards. The purpose of the tool is to compare what each ward actually achieved against what was expected and then label the performance level so that managers can quickly understand where attention is needed. Operational teams often rely on manual checking methods such as reviewing spreadsheets or reading reports line by line. While these methods work, they become difficult when operations grow larger. Manual reviews also increase the risk of missing early warning signs or identifying issues too late. The tracking tool helps solve this challenge by automatically reviewing performance numbers and calculating how close each area is to its target. It then places each area into an easy-to-understand category: normal performance, warning level performance, or critical performance. Instead of reading many reports, managers receive a clear summary of where operations are healthy and where intervention may be needed. The biggest advantage is speed. A manual process requires someone to collect information, compare values, and decide whether a problem exists. This system performs those checks immediately and consistently. It allows teams to identify weak performance sooner and focus attention where resources are needed most. For deployment, I recommend integrating this process into the hospital operations department reporting workflow. Daily performance information from each ward could automatically feed into the system so supervisors receive a dashboard or report at the start of each day. This would support faster decisions, reduce delays, and improve overall operational visibility.
